Task Analysis Using AI Tools

Rate the Order and Resolve Delivery Issues

Domain: Online Food Delivery Mobile Application

1. User Task (For Reference)

Goal:

Provide feedback on the experience and resolve any problems (missing items, wrong order, late delivery, quality issues) through refunds or credits.

Primary Actor:

A customer after receiving, or failing to receive, their order.

Trigger:

The order is marked delivered, or a problem is noticed upon opening it.

Preconditions:

An order exists in a delivered or near-delivered state.

Basic Flow:

1. Receive the delivery and inspect the order.
2. Rate the restaurant and/or courier.
3. If an issue is found, open the support/help flow.
4. Select an issue category and submit evidence (e.g., a photo).
5. Request a refund or credit.
6. Receive a resolution from support.

Postcondition:

Feedback is submitted and/or the issue is resolved with a refund or credit.

2. Competitive Products for Reference (Shortcomings)

Product	Identified Shortcoming
DoorDash	**An automated chatbot loops through generic FAQs before allowing escalation to a human agent.**
Uber Eats	**Refund policy is opaque; users are unsure whether an automatic credit or a reviewed refund will apply.**
Grubhub	**The rating prompt appears before the user has actually opened and inspected the food.**
Zomato	**No structured photo-upload flow for proving damaged or missing items, lengthening dispute resolution.**
Swiggy	**Refund credits are locked to the in-app wallet only, with no cash/card refund option.**

3. Human Factors and Environmental Considerations

- Emotional: high frustration when food is wrong, late, or missing, especially when hungry, requiring empathetic, fast-resolving UI and copy.
- Cognitive: users want a minimal number of steps to report an issue while already frustrated; long forms increase abandonment.

-

Physical: capturing evidence photos of food/packaging often happens under poor lighting (home kitchen at night).
- Trust: repeated minor issues erode long-term trust in the platform; users compare complaint-process friction across apps.
- Social: users may vent on social media if in-app resolution feels inadequate, amplifying reputational risk.

4. Pain Points, Challenges, and Tools Used by Users

Pain Points:

- Chatbot loops that delay reaching a human agent.
- Unclear refund policy and resolution timeline.
- Rating prompts that appear before the order is inspected.
- Cumbersome evidence submission (no structured photo upload).
- Refunds restricted to in-app wallet credit only.

Challenges:

- Balancing fraud prevention with fast, low-friction resolution.
- Timing the rating prompt appropriately after delivery.
- Offering flexible refund methods (cash/card vs. credit).

Tools Used by Users:

- In-app help/support chat.
- Phone camera for evidence photos.
- Email and order receipts as records.
- Social media or public reviews as an escalation tool.
- Banking/payment apps to verify refunds.
